Project Alpha

Enterprise Application Modernization Project

Document ID	PRJ-ALPHA-001
Version	1.4
Owner	Engineering
Review Cycle	Weekly

Key Facts

Item	Details
Status	In Progress
Current phase	Integration testing
Backend	Python
Frontend	React
Database	PostgreSQL
Delivery	CI/CD
Planned rollout	September 2026, subject to validation and approval

1. Project Overview

Project Alpha is an internal enterprise application modernization project. The initiative is focused on replacing selected legacy application components with a more maintainable service-oriented architecture.

The project team is coordinating application development, testing, security validation, deployment preparation, and business acceptance.

2. Objectives

The main objective is to modernize selected application components while preserving required business functionality.

Additional objectives include improving maintainability, establishing an automated delivery process, and preparing the application for controlled production rollout.

3. Technology Stack

Project Alpha uses Python for selected backend services and React for the web-based frontend.

PostgreSQL is used as the primary relational database. The team uses a CI/CD process for automated build, test, and deployment activities.

4. Development and Testing

Development work is organized around application migration and service implementation. Automated testing is incorporated into the delivery workflow.

The current project phase is integration testing. During this phase, the team verifies that the migrated components and dependent services work together correctly.

5. Current Status

Project Alpha is currently in the integration testing phase. The team is tracking integration issues, test results, security validation activities, dependencies, and business acceptance requirements.

The project is still in progress and should not be described as production-complete.

6. Planned Production Rollout

The planned production rollout is September 2026. This is a planned target rather than a guaranteed release date.

Production rollout requires successful completion of integration testing, security validation, and business approval. If these conditions are not satisfied, the rollout may be delayed.

7. Risks and Dependencies

Key dependencies include successful integration testing, security validation, environment readiness, and business approval.

Testing issues or unresolved security findings may affect the planned rollout schedule.

8. Status Review

The project team conducts a weekly status review to track progress, risks, dependencies, completed work, and upcoming milestones.

The weekly review is used to communicate the current state of the project to relevant stakeholders and to identify actions required before the next milestone.
